Reflective Journal — NewsBot 2.0 Final Project

ITAI 2373 — Final Project
Student: Mary Ann Mastri
Group: Individual
Date: May 2, 2025

Introduction

The development of NewsBot 2.0 was a challenging and rewarding experience that pushed me to integrate multiple advanced NLP components into a cohesive, production-ready system. This reflective journal documents the journey from the midterm version to the final project, highlighting the technical struggles, debugging challenges, architectural decisions, breakthroughs, and personal growth that occurred along the way.

Early Challenges and System Architecture

The first major challenge was transforming the midterm NewsBot—which consisted of several independent components—into a unified, modular architecture. The midterm version worked, but it lacked structure and scalability. For the final project, I needed a system that could:

- Run end-to-end analysis
- Support multilingual processing
- Handle conversational queries
- Generate insights across multiple articles
- Pass a full test suite

Designing the **NewsBotSystem wrapper** was the first breakthrough. Once the architecture was clearly defined, each component had a place and a purpose. This structure made the rest of the project significantly easier to manage.

Debugging and Integration Issues

One of the most persistent struggles was **integration bugs**—especially when components interacted in unexpected ways.

Missing Methods and Attribute Errors

A recurring issue was the system failing with errors like:

```
AttributeError: 'EntityRelationshipMapper' object has no
attribute 'map_relationships'
```

This happened because the method existed in the notebook but was accidentally placed **outside the class** due to indentation. Fixing this required carefully rewriting the entire class cell and ensuring the method was properly nested.

Another major issue was:

```
AttributeError: 'ConversationalInterface' object has no
attribute 'analyze_article'
```

This error broke the final demo. The fix involved adding a wrapper method inside the ConversationalInterface that forwarded calls to the system's main analysis pipeline. This was a turning point because it restored compatibility with the demo and the evaluator.

Multilingual Processing Difficulties

The multilingual layer introduced its own set of challenges. Language detection and translation worked well individually, but integrating them into the full pipeline required careful handling of:

- Encoding issues
- Non-English punctuation
- spaCy model limitations
- Translation consistency

One specific challenge was ensuring that **NER worked correctly after translation**. The solution was to create a **MultilingualNER wrapper** that translated text to English, performed NER, and returned results in a consistent format. This wrapper became a crucial part of the system.

Semantic Search and Embedding Management

The semantic search engine was powerful but required careful management of embeddings. One issue was that embeddings were being overwritten when Cell 15 re-instantiated the SemanticSearchEngine. This caused the search engine to lose its encoded documents.

The fix was to rewrite Cell 15 so it **did not overwrite components created in Cell 14**. This preserved the encoded embeddings and stabilized the system.

Testing and Performance Challenges

The test suite revealed several hidden issues:

Integration Test Failures

The integration test required the system to return:

- classification

- topics
- sentiment
- entities
- relationships
- summary

Missing even one field caused the test to fail. This forced me to carefully inspect the output structure and ensure consistency across all components.

Performance Test

The performance test required the system to run multiple times without errors. Early versions failed due to:

- Missing methods
- Slow translation calls
- Inconsistent return formats

After debugging and optimizing, the system passed all performance tests reliably.

Victories and Breakthroughs

Despite the challenges, there were several key victories:

1. Full End-to-End Pipeline Working

Seeing the `analyze_article()` method return a complete, structured analysis was one of the most satisfying moments of the project.

2. Conversational Interface Functionality

The conversational interface transformed the system from a technical tool into an interactive assistant. Once the intent classifier and routing logic were stable, the system felt polished and user-friendly.

3. Multilingual Support

Getting the system to analyze Spanish, French, and other languages felt like a major achievement. This feature significantly expanded the system's real-world applicability.

4. Insights Engine

The ContentEnhancer's ability to generate insights across multiple articles added a layer of intelligence that went beyond basic NLP tasks.

Personal Growth and Learning

This project strengthened my skills in:

- Modular software design
- Debugging complex systems
- NLP model integration
- Multilingual processing
- Testing and evaluation
- Documentation and presentation

I also learned the importance of **clear architecture**, **consistent data structures**, and **careful debugging**. Many issues were not caused by complex algorithms but by small inconsistencies—missing methods, indentation errors, overwritten components, or mismatched return formats.

Conclusion

The development of NewsBot 2.0 was a challenging but deeply rewarding experience. The project required creativity, persistence, and problem-solving across multiple layers of NLP and system design. In the end, I built a robust, multilingual, production-ready news intelligence system that meets all final project requirements and demonstrates advanced technical capability.

This project not only strengthened my understanding of NLP but also improved my confidence in building complex, real-world AI systems.
